12 Supporting Information Text

13 1. Details about the Bird Migration Datasets

14 **A. Dataset 1: American Region Bird path.** We have compiled a data set of 620 observations from online resources (1), where we
15 specifically focused on the. Birds of the American region. The dataset contains six bird species' names, migration path latitude,
16 longitude, and observation date. The dataset contains different bird species' names, migration path latitudes, longitude, and
17 observation dates.

- 18 • **Swainson's hawk:** The Swainson's hawk is a raptor with a thin body and narrow wings that migrates impressive
19 distances. Swainson's hawks rely heavily on thermals and typically avoid crossing water from which thermals rarely rise.
20 The entire population of Swainson's hawks must migrate through the narrow land bridge between North and South
21 America, often in massive flocks of hundreds of thousands of birds. During their journey from North America to South
22 America.
- 23 • **Black-Bellied Plover:** The Black-bellied Plover is Washington's largest plover. Their breeding habitat is Arctic islands
24 and coastal areas throughout the northern coasts of Alaska, Canada, and Russia. They nest on the ground in a dry, open
25 tundra with good visibility; the nest is a shallow gravel scrape. They migrate to winter in coastal areas all through the
26 world. In the New World, they winter from southwest British Columbia and Massachusetts south to Argentina and Chile.
- 27 • **Black-crowned night heron:** Black-crowned Night-Herons often spend their days perched on tree limbs or concealed
28 among foliage and branches. These social birds roost and nest in groups, although they typically forage independently.
29 Look for them in most wetland habitats across North America, including estuaries, marshes, streams, lakes, and reservoirs.
- 30 • **Brown pelican:** Brown Pelicans live along southern and western sea coasts and are rarely seen inland (except at the
31 Salton Sea in California, where they are regular in large numbers). They nest in colonies, often on isolated islands free of
32 land predators. On the Pacific Coast, Brown Pelican adults have red skin on their throats in the breeding season. On the
33 Atlantic and Gulf Coasts, Brown Pelicans are slightly smaller, and their throat skin is greenish-black.
- 34 • **Long-billed curlew:** The long-billed curlew (*Numenius americanus*) is a large North American shorebird of the family
35 Scolopacidae. This species was called the "sickle-bird" and the "candlestick bird." The species breeds in central and
36 western North America, migrating southward and coastward for the winter.
- 37 • **Pacific loon:** Pacific Loons Nests in freshwater lakes in arctic and subarctic tundra and taiga. Winters in coastal ocean
38 waters, bays, and estuaries. Occasionally, migrants appear in inland bodies of water, especially large reservoirs.

39 The dataset is taken from <https://nationalzoo.si.edu/migratory-birds/migratory-birds-tracking-map>

40 2. Methods

41 **A. Haversine formula and Computation of Directional Change in Bird Path on Earth Surface (Column θ).** We require the
42 Haversine formula (see, for example, (2)) to compute the Column θ , a Directional change in the bird's migration path.

43 The Haversine formula is an exact way to compute distances between two points on the surface of a sphere. This formula is
44 essential for navigation. It is a particular case of a more general formula in spherical trigonometry. The law of haversines
45 relates the sides and angles of spherical triangles. The formula uses the latitude and longitude of the two points. The haversine
46 formula is a re-formulation of the spherical law of cosines, but the formulation in terms of haversines is more beneficial for
47 small angles and distances. For details, we refer to (3), (4). Applying the Haversine formula, we can accurately compute the
48 direction between two points on a sphere. The mathematical form is

$$49 \cos \theta = \sin \phi_A \sin \phi_B + \cos \phi_A \cos \phi_B \cos \Delta L \quad [1]$$

50 where $\Delta L = L_A - L_B$. Point A will have latitude ϕ_A and longitude L_A . Similarly, point B will have latitude ϕ_B and
51 longitude L_B .

52 **B. World Magnetic Model.** The World Magnetic Model (WMM) provides a comprehensive representation of the Earth's magnetic
53 field on a global scale (5). This model utilizes a spherical harmonic expansion up to the 12^{12} degree and order, capturing
54 the magnetic scalar potential generated by the Earth's core. The model's expansion contributes to the geomagnetic main field. Alongside the 168
55 spherical-harmonic "Gauss" coefficients, the model incorporates an equal number of spherical-harmonic Secular-Variation (S.V.)
56 coefficients. All quantities in this section adhere to the following measurement conventions: angles are in radians, lengths are
57 in meters, magnetic intensities are in nanoteslas (nT, where one tesla is one weber per square meter or one $\text{kg}\cdot\text{s}^{-2}\cdot\text{A}^{-1}$), and
58 times are in years (6) (7).

59 The primary magnetic field B_m is a potential field and can, therefore, be expressed in geocentric spherical coordinates
60 (longitude λ , latitude ϕ' , radius r) as the negative spatial gradient of a scalar potential.

$$62 B_m(\lambda, \phi', r, t) = -\nabla V(\lambda, \phi', r, t) \quad [2]$$

63 where t represents the time. The potential can be expressed as a series expansion in spherical harmonics: (8).

$$64 \quad V(\lambda, \phi', r, t) = a \left(\sum_{n=1}^N \sum_{m=1}^M \left(\frac{a}{r}\right)^{n+1} (g_n^m(t) \cos(m\lambda) \right. \quad [3]$$

$$\left. + h_n^m(t) \sin(m\lambda) \check{p}_n^m(t) (\sin \phi') \right)$$

65 We selected $N = 36$ as the truncation level for the internal expansion of the World Magnetic Model. Here, 'a' (6371200 m)
66 represents the geomagnetic reference radius, closely approximating the mean Earth radius. The variables (λ, ϕ', r) denote the
67 longitude, latitude, and radius in a spherical geocentric reference frame, respectively. Additionally, $g_n^m(t)$ and $h_n^m(t)$ represent
68 the time-dependent Gauss coefficients of degree n and order m , describing the Earth's main magnetic field. The parameters are
69 defined as follows: (9)

$$70 \quad g_n^m(t) = g_n^m + \dot{g}_n^m(t - t_0) + \ddot{g}_n^m(t - t_0)^2 \quad [4]$$

$$71 \quad h_n^m(t) = h_n^m + \dot{h}_n^m(t - t_0) + \ddot{h}_n^m(t - t_0)^2 \quad [5]$$

72 In this equation, $g_n^m, h_n^m, \dot{g}_n^m, \dot{h}_n^m, \ddot{g}_n^m, \ddot{h}_n^m$ from Equation 4 are considered constants. For any real number μ , $\check{p}_n^m(\mu)$ represents
73 the Schmidt semi-normalized associated Legendre functions and is defined as:

$$74 \quad \check{p}_n^m(\mu) = \sqrt{2 \frac{(n-m)!}{(n+m)!}} p_{n,m}(\mu) \quad , \text{if } m > 0 \quad [6]$$

$$75 \quad \check{p}_n^m(\mu) = p_{n,m}(\mu) \quad , \text{if } m = 0 \quad [7]$$

76 Finally, in the case of a data set containing hourly mean observatory data, offsets must be incorporated at each observatory to
77 consider the local magnetic field, primarily induced in the Earth's crust, which is beyond the model's scope. Consequently, at a
78 given observatory, the magnetic field (B) is described as follows:

$$79 \quad B_m(\lambda, phi', r, t) = -\nabla V(\lambda, phi', r, t) + O(\lambda, phi', r, t). \quad [8]$$

80 The offset vector $O(\lambda, \phi', r, t)$, commonly known as the crustal bias, remains constant over time. The parameterization
81 above is employed to model datasets selected from satellite measurements and hourly mean values observed at the observatory.
82 The equations governing the internal component of the field are:

$$83 \quad X'(\lambda, \phi', r, t) = -\frac{\partial V}{r \partial \phi'} = -\sum_{n=1}^N \left(\frac{a}{r}\right)^{n+2} \sum_{m=0}^M (g_n^m(t) \cos(m\lambda) \quad [9]$$

$$+ h_n^m(t) \sin(m\lambda)) \frac{d\check{p}_n^m(\sin \phi')}{d\phi'}$$

$$84 \quad Y'(\lambda, \phi', r, t) = -\frac{\partial V}{r \cos \phi' \partial \lambda}$$

$$85 \quad = \frac{1}{r \cos \phi'} \sum_{n=1}^N \left(\frac{a}{r}\right)^{n+2} \sum_{m=0}^M m (g_n^m(t) \cos(m\lambda) + \quad [10]$$

$$h_n^m(t) \sin(m\lambda)) \check{p}_n^m(\sin \phi')$$

$$86 \quad Z'(\lambda, \phi', r, t) = \frac{\partial V}{\partial r} = -\sum_{n=1}^N (n+1) \left(\frac{a}{r}\right)^{n+2} \sum_{m=0}^M (g_n^m(t) \cos(m\lambda) \quad [11]$$

$$+ h_n^m(t) \sin(m\lambda)) \check{p}_n^m(\sin \phi')$$

87 The equations above, with the magnetic field vector observations on the left-hand side, constitute the system of condition
88 equations. Consequently, if there are d data points, the system comprises d linear equations involving the p parameters of the
89 parent model:

$$90 \quad y = Am, \quad [12]$$

91 Where \mathbf{y} is the column vector $(d \times 1)$ of observations, \mathbf{A} is the matrix $(d \times p)$ of coefficients corresponding to the unknowns,
92 which are functions of position, and \mathbf{m} is the column vector $(p \times 1)$ of unknowns, representing the Gauss coefficients of the
93 model. Since there are more observations than unknowns $(d > p)$, the system is over-determined and, thus, does not have an
94 exact solution. The final main-field coefficients for 2005.0 were obtained by polynomial extrapolation of the main-field Gauss
95 coefficients from the parent model to this date, using Equation 4. Equations 9, with the time-varying Gauss coefficients g_n^m, h_n^m
96 replaced by their time derivatives \dot{g}_n^m, \dot{h}_n^m , were then utilized to determine the final secular-variation coefficients.(10)

C. Spatio-temporal Calculation of the Position of Sun and Moon. The mentioned research hypothesis, if valid, gives us a new model used to understand Migrating bird paths depend on the sun's position as birds use the sun's position in the sky as a compass to navigate their way during their migratory journeys. The results indicate that the proposed model can estimate the Position of the Sun concerning the change of longitude, latitude, and day of the year.

D. Calculation for the zenith and azimuth angles for Sun and Moon. Suppose the observer's coordinates, or latitude and longitude, are (ϕ_0, λ_0) , and the subsolar point's coordinates are (ϕ_s, λ_s) , then the x-, y- and z-components of the unit vector, S , pointing from the observer to the center of the Sun.

- $\phi_s = \delta$
- $\lambda_s = -15(T_{GMT} - 12 + E_{min}/60)$
- $S_x = \cos \phi_s \sin(\lambda_s - \lambda_0)$
- $S_y = \cos \phi_0 \sin \phi_s - \sin \phi_0 \cos \phi_s \cos(\lambda_s - \lambda_0)$
- $S_z = \cos \phi_0 \sin \phi_s - \cos \phi_0 \cos \phi_s \cos(\lambda_s - \lambda_0)$

In this context, the influence of parallax is disregarded, effectively assuming an infinite Earth-Sun distance. It can be demonstrated that this assumption holds, and as such, there exists. $S_x^2 + S_y^2 + S_z^2 = 1$
Here T_{GMT} is the Greenwich Mean Time or UTC

Remark 1. *The derivation of S_x , S_y , and S_z becomes straightforward when working within the Earth-Centered Earth-Fixed (ECEF) (12) coordinate system. The ECEF system is a geocentric right-handed Cartesian system, and the process can be outlined as follows:*

Begin at the subsolar point in the ECEF system and construct a unit vector pointing upward. At the observer's coordinates in the ECEF system, create three unit vectors pointing east, north, and upward, respectively. Compute the dot product of each unit vector with the vector from Step 1 to obtain the right-hand sides of S_x , S_y , and S_z . Please note that this procedure disregards the influence of parallax, assuming an infinite Earth-Sun distance for simplicity and ease of calculation.

The solar zenith angle is now simply

$$Z = \cos^{-1} S_z \quad [13]$$

and the solar azimuth angle following the South-Clockwise convention is

$$\gamma_s = \tan^{-1} \left(\frac{-s_x}{-s_y} \right) \quad [14]$$

Remark 2. *The azimuth angle of the sun and moon provides valuable directional information relative to an observer, measured in degrees clockwise from the north. It reveals their lateral positions in the sky. The sun's azimuth angle continuously changes throughout the day as it moves across the sky. It starts at 90 degrees (east) during sunrise, increases until solar noon (varies by location and time of year), and sets at 270 degrees (west) during sunset. At solar noon, the sun is due south in the northern hemisphere and north in the southern hemisphere. Similarly, the azimuth angle of the moon changes as it orbits the Earth. During a full moon, it rises around 90 degrees, reaches its highest point at approximately 180 degrees, and sets at 270 degrees. During a new moon, the moon's azimuth at rising and setting aligns more closely with the sun's position. In conjunction with the altitude angle (vertical angle above the horizon), the azimuth angle allows observers to precisely determine the sun and moon's positions in the sky at any time and location. This knowledge is crucial for various applications, including astronomy, navigation, and aligning solar panels for maximum sunlight exposure.*

Remark 3. *The Sun's zenith angle is the angle between the Sun and the vertical point directly above an observer on Earth. At solar noon, it is 0 degrees when the Sun is directly overhead. During sunrise and sunset, it is 90 degrees when the Sun is at the horizon. The zenith angle changes throughout the day due to Earth's rotation and varies with the observer's location, time of year, and time of day. It is crucial for solar energy applications, affecting the amount of solar and lunar position change.*

To compute the column Z and γ_s of dataset 2, we use the position of the Sun for each species. For a given bird species, we sort the dataset concerning latitude. Then, we took the first difference of magnitude of the Sun Position (computed using the formulae discussed before).

3. Detail of Von Mises Fisher Mixture Model Fit for the Two Datasets

A mixture model is a probabilistic model for representing the presence of sub-populations within an overall population without requiring that an observed data set identify the sub-population to which an individual observation belongs. However, while problems associated with "mixture distributions" relate to deriving the properties of the overall population from those of the sub-populations, "mixture models" are used to make statistical inferences about the properties of the sub-populations given only observations on the pooled population, without sub-population identity information.

Table S35. Table containing the Bayesian Information Criteria Score for Each K value. From that, seven partitions can combine Fisher von Mises Distribution for the location parameter(Longitude and Latitude). We checked ten values of k from 1 to 10, where the optimal number of partitions is 8. This will give us the weights(ϕ) or α values as 0.154732262, 0.148760330, 0.033057697, 0.051891329, 0.363624344, 0.156100218, 0.083569358, 0.008264462 This is done for the bird species *Black Bellied Plover*

This sophisticated statistical methodology empowered us to delve into the intricate dependencies and patterns ingrained within the directional data, adeptly accommodating the circular nature inherent in our measurements. Through the application of Circular Regression, we unearthed nuanced trends and associations that might have otherwise eluded detection. We took the median value for each grid for each species.

The adoption of grid-wise partitioning offers a myriad of advantages in the realm of data analysis:

1. **Streamlined Complexity:** Partitioning the dataset into discrete grids serves to streamline the analytical process by significantly reducing the complexity of the dataset. Rather than grappling with a multitude of individual data points, our focus narrows to aggregated data within each grid, facilitating enhanced manageability and interpretability.
2. **Enhanced Visualization:** Grid-based partitioning affords enhanced visualization capabilities, allowing for the elucidation of spatial patterns and trends with heightened clarity. By condensing data within each grid, we can craft visually compelling representations, such as heatmaps or contour plots, offering profound insights into the distribution and variation of data across the study area.
3. **Augmented Statistical Analysis:** The aggregation of data within grids fosters a more robust statistical analysis

Table S45. Based on our supervised partitions where all the parameters follow von Mises distribution, we performed the circular regression and the correlation test in the above table for *Pacific loon*

B. Canonical Correlation. Canonical correlation analysis (CCA) is a statistical method that explores the linear relationship between two sets of variables. In our analysis X vector representing variables in the first set which are the Magnetic, Solar and Lunar changes, and Y be a vector representing variables in the second set which is the change of bird position. The objective of CCA is to find linear combinations of X and Y , denoted as $U = Xa$ and $V = Yb$, such that the correlation between U and V is maximized. Mathematically, this can be expressed as:

Parameter	Test Statistics	Critical Value	Distribution
θ (Bird directional change)	0.033	0.081	vonMises
Longitude	1.352	0.142	Not vonMises
Latitude	1.008	0.11	Not vonMises
Lunar azimuth difference	0.0383	0.09	vonMises
Solar Azimuth difference	0.1481	0.11	Not vonMises
Solar Zenith difference	0.0534	0.09	vonMises
Magnetic Declination	1.7933	0.164	Not vonMises

Table S46. Used Watson test on all the directional parameters of the bird species *Long Bellied curlew* where all of the mentioned parameters follow von Mises distribution for 0.01 significance level. This table is done for the first supervised partition of the species where we took the 1 to 50th observations .

Parameter	Test Statistics	Critical Value	Distribution
θ (Bird directional change)	0.0194	0.081	vonMises
Longitude	0.3383	0.09	Not vonMises
Latitude	0.3524	0.09	Not vonMises
Lunar azimuth difference	0.0673	0.081	vonMises
Solar Azimuth difference	0.0388	0.11	vonMises
Solar Zenith difference	0.0723	0.11	vonMises
Magnetic Declination	2.2371	0.142	Not vonMises

Table S47. Used Watson test on all the directional parameters of the bird species *Long Bellied curlew* where all of the mentioned parameters follow von Mises distribution for 0.01 significance level. This table is done for the first supervised partition of the species where we took the 1 to 50th observations .

K	BIC Values	K	BIC Values
1	-829.2649	11	-1267.5782
2	-1054.1596	12	-1296.8095
3	-1189.9874	13	-1291.6324
4	-1194.7899	14	-1265.8217
5	-1223.4830	15	-1276.4488
6	-1233.1482	16	-1229.4502

8	-1238.6233	18	-1278.2504
9	-1266.8802	19	-1256.7196
10	-1268.8967	20	-1184.2690

Table S48. Table containing the Bayesian Information Criteria Score for Each K value. From that, seven partitions can combine Fisher von Mises Distribution for the location parameter(Longitude and Latitude). We checked ten values of k from 1 to 10, where the optimal number of partitions is 8. This will give us the weights(ϕ) or α values as -829.2649, -1054.1596, -1189.9874, -1194.7899, -1223.4830, -1233.1482, -1243.2841, -1238.6233, -1266.8802, -1268.8967, -1267.5782, -1296.8095, -1291.6324, -1265.8217, -1276.4488, -1229.4502, -1276.0840, -1278.2504, -1256.7196, -1184.2690 This is done for the bird species *Long Bellied Curlew*

Part	Parameters used for regression with θ	ρ values	Correlation value	P-value
Part-1	Magnetic declination	0.2308	-0.07	0.4659
	Solar Azimuth Change	0.1808	0.003971	0.9774
	Solar Zenith Change	0.1674	0.00088	0.994
	Lunar Azimuth Change	0.24776	0.0376	0.79
Part-2	Magnetic declination	0.1744	0.0461	0.4699
	Solar Azimuth Change	0.189	0.0349	0.7418
	Solar Zenith Change	0.2015	-0.17102	0.1162
	Lunar Azimuth Change	0.1619	0.1504	0.1952

Table S49. Based on our supervised partitions where all the parameters follow von Mises distribution, we performed the circular circular regression and the correlation test in the above table for *Long Bellied curlew*

$$\text{maximize } \rho(U, V) = \text{cor}(U, V) = \frac{\text{cov}(U, V)}{\sqrt{\text{var}(U) \cdot \text{var}(V)}}$$

where ρ denotes the canonical correlation coefficient, cov denotes covariance, and var denotes variance.

The canonical correlation coefficients (r_1, r_2, \dots, r_k) are obtained as the square roots of the canonical eigenvalues of the matrix $\text{cov}(U, V)$ (16).

205 CCA aims to find k pairs of canonical variates $(U_1, V_1), (U_2, V_2), \dots, (U_k, V_k)$ that maximize the correlation, where k is
 206 the minimum of p and q , the dimensions of X and Y (17).

207 The adoption of grid-based partitioning emerges as a pivotal technique in data analysis, particularly for spatial datasets. By
 208 simplifying the intricate complexities inherent in spatial data, this methodology serves as a catalyst for more effective exploration
 209 and interpretation of spatial patterns and relationships, thereby advancing the frontiers of knowledge and understanding.

210 11. Black Bellied Plovers

211 In this table S50 we can clearly see that the correlation between Solar positional change and the *Black Bellied Plovers*
 212 directional change is the highest with the ρ value of 0.44 and the correlation test suggest inverse relation between majority
 213 of the parameters(Magnetic, Solar and Lunar positional changes). So clearly we can see a clear evidence that the physical
 214 parameters influence *Black Bellied Plovers* directional change.

Parameter	ρ Value	r Value
Solar Azimuth Change	0.3507626	-0.2236839
Magnetic declination	0.3212564	-0.2383581
Magnetic Inclination	0.322164	0.2546108
Solar Zenith Change	0.4441466	-0.2265752
Lunar Azimuth Change	0.2994615	-0.2736092

Table S50. *gridwise_bbp*

215 12. Black Crowned Night Heron

216 In this table S51 we can clearly see that the correlation between Lunar positional change and the *Black Crowned Night Heron*
 217 directional change is the highest with the ρ value of 0.60 and the correlation test suggest inverse relation between majority
 218 of the parameters(Magnetic, Solar and Lunar positional changes). So clearly we can see a clear evidence that the physical
 219 parameters influence *Black Crowned Night Heron* directional change. The magnetic field is also a important factor with ρ value
 220 of 0.53.

Parameter	ρ Value	r Value
Solar Azimuth Change	0.4256448	0.1947791
Magnetic declination	0.5393819	-0.4151493
Magnetic Inclination	0.5026821	-0.1813082
Solar Zenith Change	0.2419564	0.07140608
Lunar Azimuth Change	0.6092881	-0.6615668

Table S51. *gridwise_bcnh*

221 13. Pacific Loon

222 In this table S52 we can clearly see that the correlation between Geomagnetic change and the *Pacific Loon* directional change is
 223 the highest with the ρ value of 0.39 and the correlation test suggest inverse relation between majority of the parameters(Magnetic,
 224 Solar and Lunar positional changes). So clearly we can see a clear evidence that the physical parameters influence *Pacific Loon*
 225 directional change. The Solar positional Change is also a important factor with ρ value of 0.37.

Parameter	ρ Value	r Value
Solar Azimuth Change	0.3775842	0.3568713
Magnetic declination	0.3326586	-0.0634063
Magnetic Inclination	0.3952472	0.1996955
Solar Zenith Change	0.2518959	-0.05576555
Lunar Azimuth Change	0.3060159	-0.2035507

Table S52. *gridwise_pl*

226 14. Swainson's Hawk

227 In this table S53 we can clearly see that the correlation between Geomagnetic change and the *Swainson's Hawk* directional
 228 change is the highest with the ρ value of 0.26 and the correlation test suggest inverse relation between the parameters(Magnetic
 229 declination, and Lunar positional changes). So clearly we can see a clear evidence that the physical parameters influence
 230 *Swainson's Hawk* directional change. The Solar positional Change is also a important factor with ρ value of 0.232.
